

Assessing and Managing Agitation and Impaired Consciousness in Children with Traumatic Brain Injuries (TBIs)

Are you a health professional that works with children in the early stages of recovery following moderate to severe TBI in Australia or New Zealand?

This study aims to explore current approaches to assessing and managing impaired consciousness and agitation in children (0-18 years) who are in the early stages of recovery following moderate to severe TBI (from hospital admission to discharge from inpatient rehabilitation).

We hope that this knowledge may improve the care that children with a TBI receive in the future.

This study involves completing a 15-minute survey on REDCap.
